

Solution of Linear Systems

Investment Portfolio

You have a portfolio totaling \$200,000 and want to invest in **municipal bonds**, **blue-chip stocks**, and **speculative stocks**. The municipal bonds pay 6% annually. Over a 5-years period you expect blue-chip stocks to return 10% annually and speculative stocks to return 15% annually. You want a combined annual return of 8%, and you also want to have only one-fourth of the portfolio invested in stocks. How much should be allocated to each type of investment?

Solution

Let M represent municipal bonds, B represent blue-chip stocks, and G represent speculative stocks.

$$\begin{cases} M + B + G = 200,000 & \text{Eq 1: total investment is } 200,000 \\ 0.06M + 0.10B + 0.15G = 16,000 & \text{Eq 2: combined annual return } 8\% \text{ of } 200,000 \\ B + G = 50,000 & \text{Eq 3: } \frac{1}{4} \text{ of investment is allocated to stocks} \end{cases}$$

- **3 equations and 3 unknowns**

2

Solution of Linear Systems

Definition: System of Linear Equations.

A "system" of equations is a set or collection of equations that you deal with all together at once. The following is a **linear system of m equations and n unknowns**:

$$\left. \begin{array}{l} E_1 : \quad a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n = b_1 \\ E_2 : \quad a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n = b_2 \\ \vdots \quad \vdots \quad \vdots \quad \vdots \\ E_m : \quad a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n = b_m \end{array} \right\} \quad (\text{S})$$

The goal of this method is to weed out selective entries a_{ij} (or coefficients) of the system by performing linear combination of equations.

Example

$$\left. \begin{array}{l} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 = b_1 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 = b_2 \\ a_{31}x_1 + a_{32}x_2 + a_{33}x_3 = b_3 \end{array} \right| \iff \left. \begin{array}{l} \tilde{a}_{11}x_1 + \tilde{a}_{12}x_2 + \tilde{a}_{13}x_3 = \tilde{b}_1 \\ \tilde{a}_{22}x_2 + \tilde{a}_{23}x_3 = \tilde{b}_2 \\ \tilde{a}_{33}x_3 = \tilde{b}_3 \end{array} \right|$$

where, for $i \in \{1, \dots, m\}$ and $j \in \{1, \dots, n\}$, the constants a_{ij} are the **coefficients**, b_i the **constant terms** and x_1, \dots, x_n are the **unknowns of the system**. First we consider that there are the same number of equations and unknowns ($m = n$).

3

(*Triangular form*)

CHAPTER 1 - Part A. LINEAR ALGEBRAIC SYSTEMS

MATH 401-Section 0201

APPLICATIONS OF LINEAR ALGEBRA

FALL - 2014

1

Solution of Linear Systems

Gaussian Elimination

Gaussian Elimination is a simple, systematic algorithm to solve systems of linear equation.

Goal

The goal of this method is to weed out selective entries a_{ij} (or coefficients) of the system by performing linear combination of equations.

4

Solution of Linear Systems

Solution of Linear Systems

Gaussian Elimination

We use three operations to simplify the linear system (S):

1. Equation E_i can be multiplied by any nonzero constant λ with the resulting equation used in place of E_i . This operation is denoted $(\lambda E_i) \rightarrow (E_i)$

2. Equation E_j can be multiplied by any nonzero constant λ and added to the equation E_i with the resulting equation used in place of E_i .

This operation is denoted $(E_i + \lambda E_j) \rightarrow (E_i)$

3. Equations E_i and E_j can be transposed in order. This operation is denoted $(E_i) \leftrightarrow (E_j)$

By a sequence of these operations, a linear system can be transformed to a more easily solved linear system that has the same solution.

5

6

Example

To illustrate, consider a system of three linear equations

$$\begin{array}{l} x + 2y + z = 2 \\ 2x + 6y + z = 7 \\ x + y + 4z = 3 \end{array}$$

Solution

$$\begin{array}{l} x + 2y + z = 2 \\ 2x + 6y + z = 7 \\ x + y + 4z = 3 \end{array}$$

We solved the triangular system by the method of Back Substitution:

$$x = -3, \quad y = 2, \quad z = 1.$$

Matrices

Matrices

Definición: Matrix

A matrix is a rectangular array of numbers. We use the notation

$$A = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{pmatrix},$$

- The set of all $m \times n$ matrices is denoted by $\mathbb{R}^{m \times n}$.

Matrix Addition.

- Let $A = (a_{ij})$, $B = (b_{ij}) \in \mathbb{R}^{m \times n}$, then the sum $A + B$ is calculated entrywise:

$$A + B = (c_{ij}) \quad \text{with} \quad c_{ij} = a_{ij} + b_{ij}, \forall i = 1, \dots, m, \forall j = 1, \dots, n.$$

Multiplication by Scalars

- Let $A = (a_{ij}) \in \mathbb{R}^{m \times n}$ and $\alpha \in \mathbb{R}$ the scalar multiplication αA is given by multiplying every entry of A by c :

$$\alpha A = \alpha(a_{ij}) = (\alpha a_{ij}).$$

$$\begin{pmatrix} 1 & 2 & 1 \\ 2 & 6 & 3 \end{pmatrix}, \quad \begin{pmatrix} 1.4 & -22 & 0.5 \end{pmatrix}, \quad \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \begin{pmatrix} 2.5 & 1 \\ 2 & -8 \end{pmatrix}.$$

Example

8

7

Matrices

Matrices

Definition

Matrix Product

Let $A = (a_{ij}) \in \mathbb{R}^{m \times n}$, $B = (b_{ij}) \in \mathbb{R}^{n \times p}$. The matrix product $C = A \cdot B$ belongs to $\mathbb{R}^{m \times p}$, con

$$c_{ij} = \sum_{k=1}^n a_{ik} b_{kj}.$$

Even if both products are defined, they need not be equal, i.e., generally one has $AB \neq BA$.

Example

$$A = \begin{pmatrix} 1 & 2 \\ 0 & 3 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix}$$

9

10

$$\text{If } A = \begin{pmatrix} 2 & 1 & 5 \\ 3 & 0 & 4 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} -1 & 7 & 8 \\ 4 & 6 & 0 \\ 5 & 7 & 3 \end{pmatrix}.$$

Then, only AB is possible and we obtain:

$$AB = \begin{pmatrix} 27 & 55 & 31 \\ 17 & 49 & 36 \end{pmatrix}$$

10

Matrices

Definition

Definition: Matrix Inverse.

An $n \times n$ square matrix $A \in \mathbb{R}^{n \times n}$ is called **invertible** (also nonsingular or nondegenerate) if there exists $B \in \mathbb{R}^{n \times n}$ such that $A \cdot B = I$ and $B \cdot A = I$,

- We denote the identity matrix of order n as I_n or simply by I if the size can be trivially determined by the context. I_n is a square matrix with ones on the main diagonal and zeros elsewhere, moreover
- Matrix B is called **inverse of A** , denoted by A^{-1} .

$$A \cdot I = I \cdot A = A, \quad \forall A \in \mathbb{R}^{n \times n}.$$

- If A is invertible, then the inverse A^{-1} is uniquely determined.

Example

$$I_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad I_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

$$(A \cdot B)^{-1} = B^{-1} \cdot A^{-1}.$$

11

12

Solution of Linear Systems

Solution of Linear Systems

Back to the system

$$\begin{array}{ll} x + 2y + z = & 2 \\ 2x + 6y + z = & 7 \\ x + y + 4z = & 3 \end{array}$$

We can write the above system as $A\mathbf{x} = \mathbf{b}$ with

$$A = \begin{pmatrix} 1 & 2 & 1 \\ 2 & 6 & 1 \\ 1 & 1 & 4 \end{pmatrix} \quad \mathbf{x} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} \quad \mathbf{b} = \begin{pmatrix} 2 \\ 7 \\ 3 \end{pmatrix}$$

13

14

Remark

System (S) can be written as follow:

$$\underbrace{\begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{pmatrix}}_{A=\text{coefficients matrix}} \underbrace{\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}}_{X=\text{unknowns}} = \underbrace{\begin{pmatrix} b_1 \\ b_2 \\ \vdots \\ b_m \end{pmatrix}}_{B=\text{independent terms}},$$

and we obtain the matrix form:

$$AX = B.$$

- If $b_1 = b_2 = \cdots = b_m = 0$, the above matrix equation is called **homogeneous**, and **non-homogeneous** or **inhomogeneous** otherwise.

Solution of Linear Systems

Gaussian Elimination. Regular Case

We begin by replacing the system (S) by its matrix constituents $AX = B$.

For the purpose of performing the same elementary row operations in A and B we introduce the Augmented matrix.

Definition

Given the system $AX = B$, the **augmented matrix** is given by

$$M = (A|B) \in \mathbb{R}^{m \times (n+1)}$$

$$M = (A|B) = \left(\begin{array}{cccc|c} a_{11} & a_{12} & \cdots & a_{1n} & b_1 \\ a_{21} & a_{22} & \cdots & a_{2n} & b_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} & b_m \end{array} \right) \quad \mathbf{x} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} \quad \mathbf{b} = \begin{pmatrix} 2 \\ 7 \\ 3 \end{pmatrix}$$

- System of linear equation:

$x + 2y + z =$	2
$2x + 6y + z =$	7
$x + y + 4z =$	3

- Matrix form $AX = \mathbf{b}$ with

15

16

Solution of Linear Systems

Solution of Linear Systems

Example (Cont.)

By applying elementary row operations in M we obtain:

$$M = \left(\begin{array}{ccc|c} 1 & 2 & 1 & 2 \\ 2 & 6 & 1 & 7 \\ 1 & 1 & 4 & 3 \end{array} \right) \sim N = (U|\mathbf{c}) = \left(\begin{array}{ccc|c} 1 & 2 & 1 & 2 \\ 0 & 2 & -1 & 3 \\ 0 & 0 & \frac{5}{2} & \frac{5}{2} \end{array} \right)$$

Then (1) is equivalent to $U\mathbf{x} = \mathbf{c}$, where the coefficient matrix U is upper triangular, namely, $u_{ij} = 0$ whenever $i > j$.

Definition

A square matrix A will be called regular if the algorithm successfully reduces it to upper triangular U with all non-zero pivots on the diagonal.

17

Elementary Matrices

A key observation is that elementary row operations can be realized by matrix multiplication.

Example.

$$A = \left(\begin{array}{ccc} 1 & 2 & 1 \\ 2 & 6 & 1 \\ 1 & 1 & 4 \end{array} \right) \xrightarrow{(R_2-2R_1) \rightarrow R_2} \left(\begin{array}{ccc} 1 & 2 & 1 \\ 0 & 2 & -1 \\ 1 & 1 & 4 \end{array} \right)$$

$$\underbrace{\left(\begin{array}{ccc} 1 & 0 & 0 \\ -2 & 1 & 0 \\ 0 & 0 & 1 \end{array} \right)}_E \left(\begin{array}{ccc} 1 & 2 & 1 \\ 2 & 6 & 1 \\ 1 & 1 & 4 \end{array} \right) = \left(\begin{array}{ccc} 1 & 2 & 1 \\ 0 & 2 & -1 \\ 1 & 1 & 4 \end{array} \right)$$

18

Solution of Linear Systems

Example.

$$A = \left(\begin{array}{ccc} 1 & 2 & 1 \\ 2 & 6 & 1 \\ 1 & 1 & 4 \end{array} \right) \xrightarrow{(R_2-2R_1) \rightarrow R_2} \left(\begin{array}{ccc} 1 & 2 & 1 \\ 0 & 2 & -1 \\ 0 & -1 & 3 \end{array} \right) \xrightarrow{(R_3+\frac{1}{2}R_2) \rightarrow R_3} \left(\begin{array}{ccc} 1 & 2 & 1 \\ 0 & 2 & -1 \\ 0 & 0 & \frac{5}{2} \end{array} \right)$$

$$\text{If we set } E_1 = \left(\begin{array}{ccc} 1 & 0 & 0 \\ -2 & 1 & 0 \\ 0 & 0 & 1 \end{array} \right), \quad E_2 = \left(\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ -1 & 0 & 1 \end{array} \right), \quad E_3 = \left(\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & \frac{1}{2} & 1 \end{array} \right)$$

we obtain that when

$$A = \left(\begin{array}{ccc} 1 & 2 & 1 \\ 2 & 6 & 1 \\ 1 & 1 & 4 \end{array} \right), \quad \text{then } E_3 E_2 E_1 A = U = \left(\begin{array}{ccc} 1 & 2 & 1 \\ 0 & 2 & -1 \\ 0 & 0 & \frac{5}{2} \end{array} \right).$$

19

Solution of Linear Systems

Inverse elementary matrix.

To undo the operation of adding c times row j to row i , we must perform the inverse row operation that subtract c times row j from row i .

Example.

$$\underbrace{\left(\begin{array}{ccc} 1 & 0 & 0 \\ -2 & 1 & 0 \\ 0 & 0 & 1 \end{array} \right)}_{E_1} \left(\begin{array}{ccc} 1 & 2 & 1 \\ 2 & 6 & 1 \\ 1 & 1 & 4 \end{array} \right) = \left(\begin{array}{ccc} 1 & 2 & 1 \\ 0 & 2 & -1 \\ 1 & 1 & 4 \end{array} \right)$$

then

$$\underbrace{\left(\begin{array}{ccc} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 0 & 0 & 1 \end{array} \right)}_{L_1} \left(\begin{array}{ccc} 1 & 2 & 1 \\ 0 & 2 & -1 \\ 1 & 1 & 4 \end{array} \right) = \left(\begin{array}{ccc} 1 & 2 & 1 \\ 2 & 6 & 1 \\ 1 & 1 & 4 \end{array} \right)$$

20

Solution of Linear Systems

Solution of Linear Systems

Inverse elementary matrix.

To undo the operation of adding c times row j to row i , we must perform the inverse row operation that subtract c times row j from row i .

Example.

The matrices L_1, L_2 and L_3 defined by

$$L_1 = \begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad L_2 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 1 \end{pmatrix}, \quad L_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & -\frac{1}{2} & 1 \end{pmatrix}$$

are the inverses of E_1, E_2 and E_3 , respectively, namely

$$L_1 E_1 = L_2 E_2 = L_3 E_3 = I.$$

21

Solution of Linear Systems

The LU Factorization

From the above example we notice that

$$\begin{aligned} LU &= (L_1 L_2 L_3)(E_3 E_2 E_1 A) = L_1 L_2 (L_3 E_3) E_2 E_1 A = L_1 L_2 I E_2 E_1 A \\ &= L_1 (L_2 E_2) E_1 A = L_1 I E_1 A = (L_1 E_1) A = IA = A. \end{aligned}$$

Conclusions

$$A = LU$$

$$\left. \begin{array}{l} L : \text{unit lower triangular} \\ U : \text{upper triangular} \end{array} \right\} LU \text{ Decomposition (of factorization) of } A.$$

- This procedure is dimension-independent, namely it works for matrices $A \in \mathbb{R}^{n \times n}$ for as long as A has $n - 1$ nonvanishing pivots.

Example

Moreover

$$L = L_1 L_2 L_3 = \begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 1 & -\frac{1}{2} & 1 \end{pmatrix}.$$

Here L is a lower triangular matrix with all the entries on the diagonal are equal to 1 (unit lower triangular matrix).

Lemma.

If L and \hat{L} are lower triangular matrices of the same size, so is their product $L\hat{L}$. Similarly, if U and \hat{U} are upper triangular matrices of the same size, so is their product $U\hat{U}$.

22

Solution of Linear Systems

The LU Factorization

- If $A = LU$, then

$$Ax = b \iff L(Ux) = b \iff \begin{cases} Ly = b, \\ Ux = y. \end{cases}$$

Therefore, to solve the system $Ax = b$ is equivalent to:

- Solve $Ly = b$ and, then,
- Solve $Ux = y$.

Both are triangular systems, lower and upper, respectively.

24

Solution of Linear Systems

Solution of Linear Systems

Solving triangular systems

Given

$$L = \begin{pmatrix} l_{11} & 0 & \cdots & 0 \\ l_{21} & l_{22} & \ddots & \vdots \\ \vdots & \vdots & \ddots & 0 \\ l_{n1} & l_{n2} & \cdots & l_{nn} \end{pmatrix} \quad \text{and} \quad U = \begin{pmatrix} u_{11} & u_{12} & \cdots & u_{1n} \\ 0 & u_{22} & \cdots & u_{2n} \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & u_{nn} \end{pmatrix}$$

L is lower triangular and U is upper triangular.

- Triangular system solving is easy because the unknowns can be resolved without any further manipulation of the matrix of coefficients.

25

Consider the following 3-by-3 lower triangular case:

$$L = \begin{pmatrix} l_{11} & 0 & 0 \\ l_{21} & l_{22} & 0 \\ l_{31} & l_{32} & l_{33} \end{pmatrix} \quad \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} b_1 \\ b_2 \\ b_3 \end{pmatrix}$$

The unknowns can be determined as follows:

$$\begin{aligned} x_1 &= b_1 / l_{11} \\ x_2 &= (b_2 - l_{21}x_1) / l_{22} \\ x_3 &= (b_3 - l_{31}x_1 - l_{32}x_2) / l_{33} \end{aligned}$$

- This is the 3-by-3 version of an algorithm known as forward substitution.
- Notice that the process requires l_{11}, l_{22}, l_{33} to be nonzero.

26

Solution of Linear Systems

Forward Substitution

- Consider the system $Lx = b$ with lower triangular matrix L . We proceed by simple forward substitution of variables:

$$\begin{cases} l_{11}x_1 &= b_1 \Rightarrow x_1 = b_1 / l_{11} \\ l_{21}x_1 + l_{22}x_2 &= b_2 \Rightarrow x_2 = (b_2 - l_{21}x_1) / l_{22} \\ \vdots & \vdots \\ l_{n1}x_1 + \cdots + l_{nn}x_n &= b_n \Rightarrow x_n = (b_n - l_{n1}x_1 - \cdots - l_{nn-1}x_{n-1}) / l_{nn} \end{cases}$$

$$\boxed{\begin{array}{l} \text{For } i = 1, \dots, n \\ x_i = \frac{1}{l_{ii}} \left(b_i - \sum_{j=i+1}^{i-1} l_{ij}x_j \right) \end{array}}$$

- Algorithm:

$$\boxed{\begin{array}{l} \text{For } i = n, n-1, \dots, 1 \\ x_i = \frac{1}{u_{ii}} \left(b_i - \sum_{j=i+1}^n u_{ij}x_j \right) \end{array}}$$

- On the other hand, consider the system $Ux = b$ with upper triangular con matrix U . Then we obtain the following algorithm:

Solution of Linear Systems

Backward Substitution

- On the other hand, consider the system $Ux = b$ with upper triangular con matrix U . Then we obtain the following algorithm:

27

28
